# 1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Orbs TWAP protocol, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contracts can be further improved due to the presence of several issues related to either security or performance. This document outlines our audit results.

### 1.1 About Orbs TWAP

The Orbs TWAP protocol implements a TWAP Order mechanism (either Limit Order or Market Order) with the possibility of partial fills. It aims to minimize a large order's impact on the market or neutralize market volatility over time by dividing trades into smaller quantities and executing them at regular intervals over time. The basic information of the audited contracts is as follows:

### 1.2 About PeckShield

PeckShield Inc. [5] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

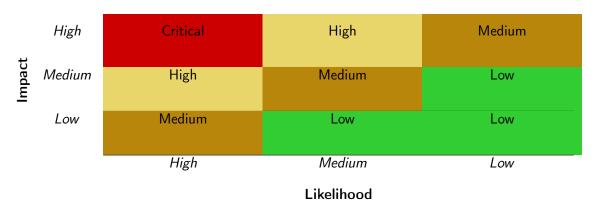

Table 1.2: Vulnerability Severity Classification

## 1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [4]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further

Table 1.3: The Full List of Check Items

deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [3], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

#### 1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary		
Configuration	Weaknesses in this category are typically introduced during		
	the configuration of the software.		
Data Processing Issues	Weaknesses in this category are typically found in functional-		
	ity that processes data.		
Numeric Errors	Weaknesses in this category are related to improper calcula-		
	tion or conversion of numbers.		
Security Features	Weaknesses in this category are concerned with topics like		
	authentication, access control, confidentiality, cryptography,		
	and privilege management. (Software security is not security		
	software.)		
Time and State	Weaknesses in this category are related to the improper man-		
	agement of time and state in an environment that supports		
	simultaneous or near-simultaneous computation by multiple		
	systems, processes, or threads.		
Error Conditions,	Weaknesses in this category include weaknesses that occur if		
Return Values,	a function does not generate the correct return/status code,		
Status Codes	or if the application does not handle all possible return/statu		
	codes that could be generated by a function.		
Resource Management	Weaknesses in this category are related to improper manage-		
	ment of system resources.		
Behavioral Issues	Weaknesses in this category are related to unexpected behav-		
	iors from code that an application uses.		
Business Logics	Weaknesses in this category identify some of the underlying		
	problems that commonly allow attackers to manipulate the		
	business logic of an application. Errors in business logic can		
	be devastating to an entire application.		
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used		
	for initialization and breakdown.		
Arguments and Parameters	Weaknesses in this category are related to improper use of		
	arguments or parameters within function calls.		
Expression Issues	Weaknesses in this category are related to incorrectly written		
	expressions within code.		
Coding Practices	Weaknesses in this category are related to coding practices		
	that are deemed unsafe and increase the chances that an ex-		
	ploitable vulnerability will be present in the application. They		
	may not directly introduce a vulnerability, but indicate the		
	product has not been carefully developed or maintained.		

# 2 | Findings

### 2.1 Summary

Here is a summary of our findings after analyzing the <code>Orbs</code> TWAP implementation. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place <code>DeFi-related</code> aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings		
Critical	0		
High	0		
Medium	1		
Low	1		
Informational	0		
Total	2		

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

### 2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 medium-severity vulnerability and 1 low-severity vulnerability.

Table 2.1: Key Orbs TWAP Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Medium	Revisited Logic of TWAP::performFill()	Business Logic	Fixed
PVE-002	Low	Incompatibility with Deflationary/Rebas-	Business Logic	Fixed
		ing Tokens		

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

# 3 Detailed Results

## 3.1 Revisited Logic of TWAP::performFill()

• ID: PVE-001

Severity: MediumLikelihood: MediumImpact: Medium

Target: TWAP

Category: Business Logic [2]CWE subcategory: CWE-841 [1]

### Description

The TWAP contract is the main entry for interaction with users. It allows the user (i.e., maker) to create a TWAP order, which breaks a larger order down into smaller trades (or chunks) that will be executed at regular intervals over a period of time. Once created, an English Auction bidding war on each chunk will be enabled. Anyone can serve as a taker by finding the best swap path on any DEX to fill the order for the chunk within the parameters set by the maker. In particular, the fill() routine is called by the winning bidder to fill the order for the chunk. After further analysis, we observe the internal performFill() routine called inside it needs to be improved.

To elaborate, we show below the related code snippet of the TWAP contract. Inside the performFill () routine, the local expectedOut variable indicates the minimum amount of dstToken that the maker of the order should receive. By design, it should be the bid amount of the winning bidder. However, we notice the minimum amount specified by the maker is incorrectly used as expectedOut (line 327). Apparently, it does not meet the design of the English Auction. Given this, we suggest to improve the implementation as below: uint256 expectedOut = o.bid.dstAmount (line 327).

```
313
314
315
        function performFill(OrderLib.Order memory o) private returns (address exchange,
            uint256 srcAmountIn, uint256 dstAmountOut, uint256 dstFee)
316
317
            require(msg.sender == o.bid.taker, "taker");
318
             require(block.timestamp < o.status, "status"); // deadline, canceled or</pre>
319
             require(block.timestamp > o.bid.time + MIN_BID_WINDOW_SECONDS, "pending bid");
320
321
             exchange = o.bid.exchange;
322
             dstFee = o.bid.dstFee;
323
             srcAmountIn = o.srcBidAmountNext();
324
             ERC20(o.ask.srcToken).safeTransferFrom(o.ask.maker, address(this), srcAmountIn);
325
             ERC20(o.ask.srcToken).safeIncreaseAllowance(exchange, srcAmountIn);
326
327
             uint256 expectedOut = o.dstMinAmountNext();
328
             dstAmountOut = IExchange(exchange).swap(srcAmountIn, expectedOut + dstFee, o.bid
329
             dstAmountOut -= dstFee;
330
             require(dstAmountOut >= expectedOut, "min out");
331
332
             ERC20(o.ask.dstToken).safeTransfer(o.bid.taker, dstFee);
333
             ERC20(o.ask.dstToken).safeTransfer(o.ask.maker, dstAmountOut);
334
```

Listing 3.1: TWAP::fill()&&performFill()

Recommendation Correct the implementation of the performFill() routine as above-mentioned.

Status The issue has been addressed in this commit: 762badc.

## 3.2 Incompatibility with Deflationary/Rebasing Tokens

• ID: PVE-002

Severity: Low

Likelihood: Low

• Impact: Low

• Target: UniswapV2Exchange/TWAP

Category: Business Logic [2]

• CWE subcategory: CWE-841 [1]

#### Description

By design, the UniswapV2Exchange contract is an adapter of DEX. In particular, one entry routine, i.e., swap(), allows the user to swap a kind of ERC20 token to another. While examining its logic, we observe the current implementation is reasonable under the assumption that the token transfer inside the routine will always result in full transfer. Otherwise, the transaction will be reverted.

```
31
        function swap (
32
            uint256 amountIn,
33
            uint256 amountOutMin,
34
            bytes calldata data
35
        ) public returns (uint256 amountOut) {
36
            address[] memory path = abi.decode(data, (address[]));
37
            ERC20 srcToken = ERC20(path[0]);
38
            srcToken.safeTransferFrom(msg.sender, address(this), amountIn);
39
            srcToken.safeIncreaseAllowance(address(uniswap), amountIn);
40
41
                uniswap.swapExactTokensForTokens(amountIn, amountOutMin, path, msg.sender,
                    block.timestamp)[
42
                    path.length - 1
43
                1:
44
```

Listing 3.2: UniswapV2Exchange::swap()

However, there exist other ERC20 tokens that may make certain customizations to their ERC20 contracts. One type of these tokens is deflationary tokens that charge certain fee for every transfer() or transferFrom(). (Another type is rebasing tokens such as YAM.) As a result, this may not meet the assumption behind these routines related to token transfer.

One possible mitigation is to measure the asset change right before and after the asset-transferring routines. In other words, instead of bluntly assuming the amount parameter in transfer() or transferFrom() will always result in full transfer, we need to ensure the increased or decreased amount in the contract before and after the transfer() or transferFrom() is expected and aligned well with our operation. Though these additional checks cost additional gas usage, we consider they are necessary to deal with deflationary tokens or other customized ones if their support is deemed necessary.

Note another routine, i.e., TWAP::performFill(), shares the same issue.

Recommendation If current codebase needs to support possible deflationary tokens, it is better to check the balance before and after the transfer()/transferFrom() call to ensure the book-keeping amount is accurate. This support may bring additional gas cost. Also, keep in mind that certain tokens may not be deflationary for the time being. However, they could have a control switch that can be exercised to turn them into deflationary tokens. One example is the widely-adopted USDT.

Status The issue has been addressed by the following commits: bac1255 and 762badc.

# 4 Conclusion

In this audit, we have analyzed the design and implementation of the Orbs TWAP, which implements a TWAP Order mechanism with the possibility of partial fills. It aims to minimize a large order's impact on the market or neutralize market volatility over time by dividing trades into smaller quantities and executing them at regular intervals over time. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
